1. Evaluation of the team members

(Please evaluate with grades the work done by your team members, and a short description of what they did.)

No	Name	*Team effort	*Time management	*General grading	Description
1	Xhoi Ikonomi	10	10	10	TEAM LEADER + frontend development
2	Ajna Nushi	10	10	10	Frontend development
3	Parashqevi Klimi	10	10	10	Backend development
4	Loric Hagard	9	10	10	M.I.A AI agent

(Explanation: * The grading given is from 1-10)

2. Comments about the work done by other members.

Parashqevi - Score: 10

Parashqevi was my partner on the backend and built much of its foundation. In the first weeks she set up the Supabase project and the full database schema, then implemented the JWT authentication system, the project structure, the Pydantic schemas, and the first professor and student routers. She also fixed two early startup bugs that were blocking everyone and later wrote the API documentation. She was organised, dependable, and easy to coordinate with.

Ajna - Score: 10

Ajna built the entire student-facing frontend to a high standard. In Week 4 she created all six dashboard tabs from scratch with real API integration, loading states, and error handling, along with the M.I.A chat interface and its session management. Throughout the project she kept refining the UI - fixing schema mismatches, adapting to backend changes, and improving mobile responsiveness. Her interfaces were consistently polished and user-friendly.

Loric - Score: 10

Loric owned the M.I.A AI agent, one of the defining features of our project, and was great at what he did. He started in Week 3 with a working chatbot using the Groq API and steadily enriched it - connecting it to student academic data, adding preferences, and persisting chats in Supabase. In the final week he added an attendance failure notification that tells a student when they have failed a course for attendance below 75%. He also handled the chatbot's documentation and testing. He was always reliable and happy to help whenever you reached out, and tended to work best independently.

Xhoi - Score: 10

Xhoi was an outstanding team leader and did an amazing job steering the project from start to finish. She made an exceptionally broad contribution, covering the full React frontend architecture as well as significant backend work. She set up the entire frontend scaffold in Week 1–2, including client-side routing for all three roles and Supabase authentication, and was the one who proposed and got the team to agree on React + Vite as the stack. Her most impactful work came in the final weeks: she completely overhauled the grading system to implement the correct Albanian 4–10 scale with proper GPA mapping, fixed the semester logic to match Albanian university norms (Spring/Autumn only), and enforced the 75% attendance threshold rule across all three dashboards with clear visual warnings. She also built the component-based grade recording system for professors, the scholarship feature in the finance module, multi-file upload support, and numerous critical bug fixes including the admin user edit failure, the MIA chat schema mismatch, and the CORS proxy configuration. As leader she kept everyone aligned and consistently went beyond her assigned role to keep the whole system working correctly and coherently — an amazing job all around.

3. Work done by me.

My role in the project was backend development and testing - building FastAPI endpoints, database models, business logic, and the validation layer, while continuously checking that the API behaved correctly. In the first weeks I set up my backend environment, learned the project architecture, and helped define how the student and admin modules would be organised, then built the initial route definitions and tested early endpoints with Postman. In Week 4 I implemented most of the student endpoints - retrieving course materials with enrollment checks, weighted GPA calculation, and assignments and submissions with related course data - and added file uploads through multipart/form-data into Supabase Storage, which is where I found and fixed the missing "submissions" storage bucket. On the admin side I built an enrollment endpoint with validation to prevent duplicate enrollments. In Week 5 I reviewed and refined the student endpoints for correctness, tested the GPA logic against edge cases, and verified that the dashboard data matched the API responses. From Week 6 onward I focused on making the backend more reliable: I went through `auth.py`, `admin.py`, and `professor.py` and replaced broad "catch everything" error handling with specific exceptions so real problems stop being hidden. That review led me into the login and security work - I removed an unsafe default fallback for the JWT secret key so the app now refuses to start without a proper one, and I cleaned up how invalid tokens are rejected. In Week 8 I unified role checking into a single shared dependency used across the admin, professor, student, and finance routes so they all return consistent 401/403 errors instead of confusing "not found" responses, and tested it with wrong, missing, and invalid tokens. In the final week I fixed three correctness bugs: a GPA calculation that still used letter grades instead of the Albanian 100-point scale, a data-isolation bug where a shared list could leak one user's data to another, and the student preferences table that was being read but never written to. I also confirmed our Supabase keys were handled safely, with the sensitive key kept on the backend and the environment file out of git.
